#### \_ '

### A very little bit about Time Series Analysis

- Given a time series, can we tell if it is chaotic (deterministic) or stochastic (produced by a non-deterministic process)? Yes
- The idea is to invert the procedure we used to generate orbits of the logistic function—use the orbits (i.e., the data) to generate the function!

 $\bullet \;$  We used a function like this to determine  $x_{n+1},$  the next x value, given  $x_n,$  the current x value.

## Real Data

• Suppose we have some real data:

 $x_1 = 14$ 

 $x_2 = 24$  $x_3 = 52$ 

A\_3 - 3.

 $x_4 = 61$  $x_5 = 42$ 

----

• Plot it as follows:

- ullet The idea is that we're plotting  $x_{n+1}$  vs.  $x_n$ .
- Do this for lots and lots of data.

# Determinism vs. Stochasticity

• If the data is deterministic, the plot will look like this:

- ullet For a given  $x_n$  there is just one  $x_{n+1}$ .
- If the data is from a non-deterministic source, the plot will look like this:

ullet For a given  $x_n$  there can be many  $x_{n+1}$ 's.

# Time Series Conclusion

- This sort of approach is a powerful and successful technique for analyzing experimental data.
- There's much, much more to it than this, however.
